

Regulated, Adjustable -2x Inverting Charge Pump

MAX868

General Description

The MAX868 inverting charge pump provides a low-cost and compact means of generating a regulated negative voltage up to $-2 \times V_{IN}$ from a positive input voltage between 1.8V and 5.5V. It uses a pulse-frequency-modulation (PFM) control scheme to generate the regulated negative output voltage. PFM operation is obtained by gating the internal 450kHz oscillator on and off as needed to maintain output voltage regulation. This unique on-demand switching scheme gives the MAX868 excellent light-load efficiency without degrading its full-load operation (up to 30mA), permitting smaller capacitors to take advantage of the oscillator's high switching frequency.

The MAX868 requires no inductors; only four capacitors are required to build a complete DC-DC converter. Output voltage regulation is achieved by adding just two resistors. The MAX868 comes in a 10-pin μ MAX package, which is only 1.11mm high and occupies just half the board area of a standard 8-pin SO.

Applications

Small LCD Panels
Cell Phones
Cordless Phones
Camcorders
Handy-Terminals, PDAs
Medical Instruments
Battery-Operated Equipment

Configuration

Features

- ♦ Regulated Negative Output Voltage (up to $-2 \times V_{IN}$)
- ♦ Ultra-Small, 10-Pin μ MAX Package
- ♦ On-Demand Switching at up to 450kHz
- ♦ 30 μ A Quiescent Supply Current
- ♦ Requires Only Four Small External Capacitors
- ♦ 1.8V to 5.5V Input Voltage Range
- ♦ 0.1 μ A Logic-Controlled Shutdown
- ♦ Up to 30mA Output Current

Ordering Information

Pin Description

PIN	NAME	FUNCTION
1	GND	Analog Ground
2	OUT	Charge-Pump Output
3	C1-	Negative Terminal of Flying Capacitor C1
4	PGND	Power Ground
5	C1+	Positive Terminal of Flying Capacitor C1
6	C2-	Negative Terminal of Flying Capacitor C2
7	IN	Supply-Voltage Input. Input voltage range is 1.8V to 5.5V.
8	C2+	Positive Terminal of Flying Capacitor C2
9	$\overline{\text{SHDN}}$	Active-Low Shutdown Input. Connect $\overline{\text{SHDN}}$ to GND to put the MAX868 in shutdown mode and reduce supply current to 0.1 μ A. Connect to IN for normal operation. OUT is actively pulled to GND in shutdown.
10	FB	Feedback Input. Connect FB to a resistor divider for a regulated output voltage. Connect to IN to generate an unregulated -2 x V_{IN} output voltage.

Detailed Description

The MAX868 inverting charge pump uses pulse-frequency-modulation (PFM) control to generate a regulated negative output voltage up to $-2 \times V_{\text{IN}}$. PFM operation is obtained by enabling the internal 450kHz oscillator as needed to maintain output voltage regulation. This control scheme reduces supply current at light loads and permits the use of small capacitors.

The functional diagram shown in Figure 1 indicates the two phases of MAX868 operation: charge phase ($\Phi 1$) and discharge phase ($\Phi 2$). In charge phase, the switches on the left-hand side close, and the switches on the right-hand side open. In the discharge phase, the inverse occurs.

Figure 2 illustrates that in charge phase, both flying capacitors are charged in parallel. The load is serviced entirely by the charge stored in the output capacitor. Figure 3 demonstrates the series connection of the flying capacitors in the discharge phase. The series combination of the flying capacitors, when connected to the output capacitor, transfers charge to the output in order to maintain output voltage regulation. In normal operation, the MAX868 operates predominantly in charge phase, switching to discharge phase only as needed to maintain a regulated output.

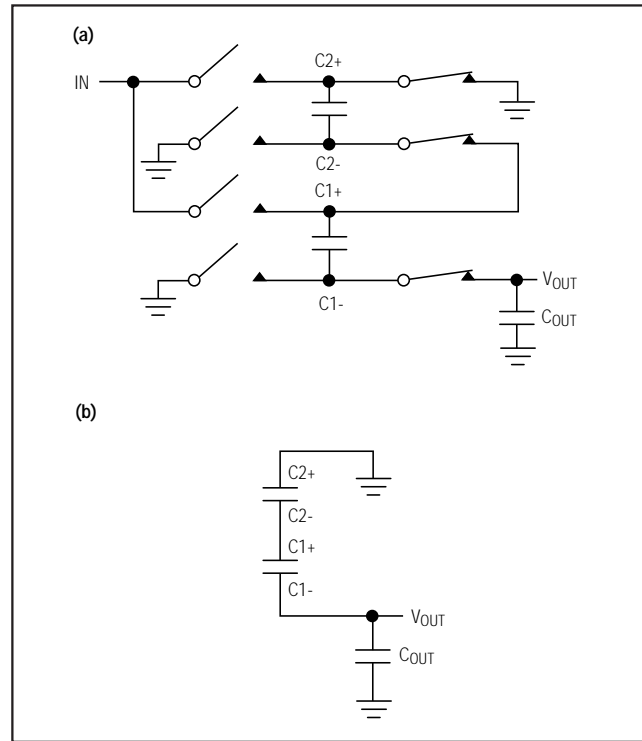

Figure 3. **a)** In discharge phase, the left-hand switches are open and the right-hand switches are closed, transferring energy from the flying capacitors (C1 and C2) to the output capacitor (COUT). **b)** The equivalent circuit of the discharge phase of operation.

Design Procedure

Setting the Output Voltage

Set the output voltage using two external resistors, R1 and R2, as shown in Figure 4. Since the input bias current at FB has a 50nA maximum, large resistor values in the feedback loop do not significantly degrade accuracy. Begin by selecting R2 in the 100k Ω to 500k Ω range, and calculate R1 using the following equation:

$$R1 = R2 \times \frac{|V_{OUT}|}{V_{REF}}$$

where VOUT is the desired output voltage, and VREF is any available regulated positive voltage. When the MAX868 is powered by a regulated voltage, VIN can be used as the reference for setting the output voltage.

When the MAX868 is powered by an unregulated supply, such as when operating directly from a battery, use any available positive reference voltage in the system. Note that due to the MAX868's doubling and inverting charge-pump action, the output voltage is limited to $-2 \times V_{IN}$.

Alternatively, to configure the MAX868 as a simple, unregulated doubler-inverter ($V_{OUT} = -2 \times V_{IN}$), connect FB to IN. In this configuration, the MAX868 runs at its maximum oscillator frequency, operating as a conventional, open-loop charge pump.

If multiple oscillator cycles are required to regulate the output, reduce the values for R1 and R2, or parallel a small capacitor (CC) across R1 to compensate the feedback loop and ensure stability. Choose the lowest capacitor value that ensures stability; values up to 47pF are adequate for most applications.

Regulated, Adjustable -2x Inverting Charge Pump

Capacitor Selection

Choosing the Flying Capacitors

Proper choice of the flying capacitors is dependent primarily upon the desired output current. For flying capacitors in the 0.1μF to 0.33μF range, the maximum output current can be approximated by the following equation:

$$I_{OUT(MAX)} = \frac{2 \times V_{IN} - |V_{OUT}|}{\frac{4}{f_{MAX} \times (C1 + C2)} + R_{OUT} \times \frac{10V}{V_{IN} + |V_{OUT}|}}$$

where f_{MAX} is the maximum oscillator frequency (typically 450kHz), R_{OUT} is the MAX868 open-loop output impedance (typically 70Ω), and $C1$ and $C2$ are the flying-capacitor values. As a general rule, choose the lowest-value flying capacitors that provide the desired output current in order to minimize output voltage ripple (see the section *Choosing the Output Capacitor*).

Surface-mount ceramic capacitors are preferred, due to their small size, low cost, and low equivalent series resistance (ESR). To ensure proper operation over the entire temperature range, choose ceramic capacitors with X7R (or equivalent) low temperature-coefficient (tempco) dielectrics. See Table 1 for a list of suggested capacitor suppliers.

Choosing the Output Capacitor

The output capacitor stores the charge transferred from the flying capacitors and services the load between oscillator cycles. A good general rule is to make the output capacitance at least ten times greater than that of the flying capacitors.

The output voltage ripple is dependent upon the capacitance of the flying capacitor and upon the output capacitor's capacitance and ESR. When operating in closed-loop mode (when the MAX868 is generating a regulated output voltage), use the following equation to approximate peak-to-peak output voltage ripple:

$$V_{RIPPLE} = (2 \times V_{IN} - |V_{OUT}|) \times \left(\frac{1}{1 + \frac{4 \times C_{OUT}}{C1 + C2}} + \frac{R_{ESR}}{R_{OUT}} \right)$$

where $C1$ and $C2$ are the flying capacitors, R_{ESR} is the output capacitor's ESR, and R_{OUT} is the MAX868's open-loop output impedance, typically 70Ω.

Choose a low-ESR output capacitor for minimum output ripple. Surface-mount ceramic capacitors are preferred for their small size, low cost, and low ESR; low-ESR tantalum electrolytic capacitors are also acceptable. When using a ceramic output capacitor, ensure proper operation over the entire temperature range by choosing a capacitor with X7R (or equivalent) low tempco dielectric. See Table 1 for a list of suggested capacitor suppliers.

Applications Information

Low-Output-Voltage Operation

Since the difference between the voltage of the series-connected flying capacitors and the output voltage must be dissipated within the device, the MAX868's efficiency is very similar to that of a linear regulator. Estimate efficiency using the following equation:

$$\eta = \frac{|V_{OUT}|}{k \times V_{IN}}$$

where k is a constant equal to 2 for the standard configuration of Figure 5 and equal to 1 for the circuit of Figure 6. This equation's denominator is the voltage resulting from the series connection of the flying capacitors ($-2 \times V_{IN}$, as shown in Figure 3b), while its numerator is simply the regulated output voltage.

For applications in which the output voltage will not be more negative than $-|V_{IN}|$, the efficiency can be doubled using the circuit of Figure 6, as compared to the circuit of Figure 5. In Figure 6, a single flying capacitor is connected between C2+ and C1-, with C2- and C1+ left

unconnected. Furthermore, doubling the flying capacitor to provide the same flying capacitance as the standard configuration (i.e., setting $C_F = C1 + C2$) provides the same load-current capability as the standard configuration and reduces the MAX868's open-loop output resistance by a factor of two, due to the reduction in the number of switches in the current path.

Layout and Grounding

Proper layout is important to obtain optimal performance. Connect GND to PGND together using the shortest trace possible, and similarly connect these pins to the ground plane. Mount all capacitors as close to the MAX868 as possible, keeping traces short to minimize parasitics. Keep all connections to the FB pin as short as possible. Specifically, locate R1 and R2 next to FB (Figures 7 and 8). Should it become necessary in the final layout, leave room to parallel a feed-forward capacitor across R1.
